TITLE: Incorporation of oxidation cathanion into MgO anode film as determined by the method of labeled atoms

SOURCE: Zhurnal prikladnoy khimii, v. 37, no. 11, 1964, 2531-2533

TOPIC TAGS: anode oxidation, anode film, magnesium alloy, aluminum alloy, magnesium oxide film, anion incorporation, phosphate incorporation, sulfate incorporation, electrolysis

ABSTRACT: Anode oxidation of magnesium alloy (ML-5) sheets was carried out in a solution containing 55g/liter NaOH and 35g/liter Na₃PO₄. To the prepared electrolyte, P32 was added as trisodiumphosphate and the reaction was carried out at 70C and a current of 1.5 A/dm². After oxidation, the samples were washed to remove free PO₄⁻³ ions and the samples were dried and counted. The counts obtained showed increasing radioactivity in the samples, indicating that there was binding of phosphate ions by the oxidized anode film. Since they could not be washed away, there is a strong union between the two. The relative content of electrolyte anion in thin films reached 5% by weight, but as the oxide film increased in thickness the relative content of phosphate ions decreased, reaching

Abstract : A study was made of the microscopic structure of the hypophysis in 36 persons. In the hypophyses of the newborn parenchymatous cells predominate, there are few eosinophilic cells, the blood vessels are thin-walled, the nerve structures are represented by a small number of naked axis cylinders. At the age of 5-10 years the quantity of stroma increases. The

Using results of testing model turbine in laboratory of VIGM, establishes that decrease in number of revolutions and even complete braking of turbine may be achieved by turning runner blades in direction of small angles at any position of guide vanes. This permits eliminating quick-action gates--for stopping turbine in emergency--which increase size of structure and cost of hydroelec stations.

Iznosostoykost' reaktivnykh gidroturboin (Wear Resistance of Hydraulic Reaction Turbines) Moscow, Gosenergoizdat, 1960. 108 p. 2500 copies printed.

Ed.: N. N. Arshenevskiy; Tech. Ed.: N. I. Borunov.

PURPOSE: This book is intended for engineers and technicians engaged in the planning and operation of hydroelectric power stations and in the design of hydraulic turbines and machinery; it may also be used by students in schools of higher technical education.

COVERAGE: Methods are presented which permit the evaluation and comparison of the degree of wear susceptibility of various types of turbines. Particular attention is focused on wear resulting from the action of hard particles suspended in water. The working processes of modern hydraulic reaction turbines are analyzed from the point of view of wear and cavitation resistance under different operating regimes. Recommendations are given for the proper selection of turbines for various mounting and operating conditions, and for design measures aimed at increasing the service life of the turbine

TITLE: The influence of various factors on the structure and properties of metal-ceramic iron-silicon alloys

CITED SOURCE: Tr. Kuybyshevsk. aviat. in-t, vy* p. 16, 1963, 201-211

TOPIC TAGS: sintered alloy, iron silicon alloy, sintered alloy property

TRANSLATION: Research was made on the influence of the silicon content, the specific pressing pressure, and the sintering temperature on the porosity and specific losses of metal-ceramic Fe-Si alloys at a frequency of 50 cps. The research was conducted by metallographic and roentgenostructural methods. The mixtures were made of Sulin Fe-powder types AK, AS, AM, and ACM, and Si75 ferrosilicon with a particle size of less than 0.04 mm in a mechanical mixer with a 0-10% silicon content. Single-layer ring-shaped samples were pressed at a specific pressure

Card 1/2

ACCESSION NR: AR4018337

of 5, 10, and 15 tons/cm². The pressed samples were sintered in an atmosphere of dissociated ammonia at 1,000-1,300 degrees for 1-28 hours. It was shown that the porosity of Fe-Si pressed parts depends upon the silicon content. An empirical equation was arrived at, which connected the relative porosity (in %) with the specific pressure of pressing (in tons/cm²) and the silicon content (in %). The x-ray structural analysis showed that after 20 hours of sintering at 1,300 degrees, the alloys become a homogeneous solid solution of silicon in alpha Fe. The specific losses change according to a curve with a dip when the silicon content is increased. The minimum losses of Plp/50 were obtained with 6-7% Si. They amount to approximately 7 watts/kg. With this composition, the minimum Hc and the maximum magnetic permeability was obtained.

PERIODICAL: NAUKA I ZHICHEN', 1957 #12, pp2 (USSR)

ABSTRACT: After the establishment of the people's democracy in bulgaria, several new scientific and medical institutes were founded, among them the higher Medical Institute imeni I. P. Pavlov (Vysshiiy meditsinskii institut imeni I. P. Pavlova) in the city of Plovdiv. Furthermore , chairs in physiology were set up at the state university at Sofia, at the Higher Veterinary-Medical Institute, at the Higher Agricultural Institute as well as physiology sections and laboratories at various scientific research institutes of the Ministry of Health. Considerably increases were also the number of chairs for pharmacology and biochemistry. The event of greatest importance for the development of theoretical , clinical and practical medicine in bulgaria was the joint session of the Bulgarian Academy of Sciences and the USSR Academy of Medical Sciences, devoted to Pavlov doctrines. The Special Pavlov Committee was founded simultaneously with this session with the aim to acquaint the bulgarian Medical Faculty with the basic principles of Pavlov's physiology.

Title : On the Influence of the Preparations of Silene "brugayskaya"
and Silene latifolia on the Gastric Secretion of Dogs

Orig Pub: Zdravookhr. Kazakhstana, 1958, № 5, 44-50

Abstract: The action of 5-15% tinctures of silene "brugayskaya" (I)
and Silene latifolia (II) and 10% alcohol tincture of
Silene "brugayskaya" (III) on gastric secretion was studied
in experiments on dogs.

I and II in a dose of 5 ml/kg induce an increase of the
amount of gastric juice up to 500% and 383.3% (respectively).

TEXT. Methods are described of total-loss measurements in specimens of ferromagnetic materials at frequencies up to 20 kcs/sec. Results are presented of comparative investigations of the calorimeter-, wattmeter and bridge- methods. Using the calorimetric method the tested specimen was placed together with the magnetizing coil in a Dewar vessel filled with transformer oil, and the losses were determined by measuring the temperature of the oil. The value of the max. magnetic induction corresponding to the measured loss was

TITLE: Luminescence properties of aluminum oxide and helenite activated by cerium under cathode-beam excitation

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya,
v. 25, no. 3, 1961, 327 - 330

TEXT: This is a reproduction of a lecture delivered at the 9th Conference on Luminescence (Crystal Phosphors), which took place in Kiev from June 20 to 25, 1960. The author studied the emission spectrum, the relative intensity of luminescence and the time of damping of cathodoluminesphores $2\text{CaO}\cdot\text{Al}_2\text{O}_3\cdot\text{SiO}_2\text{-Ce}$ and $\text{Al}_2\text{O}_3\text{-Ce}$ as a function of the amount of heavy metals (Fe, Cu, Cr) in the mixture. The aluminum oxide was used in the form of $\alpha\text{-Al}_2\text{O}_3$. All characteristics were examined with a steady electron beam at plate voltages of 15 - 17 kv and a current density of $0.1 \mu\text{a/cm}^2$. The spectrum was taken with a YM-3 (UM-3) monochromator and a photomultiplier. The intensity of the individual bands and the damping rate were measured

Card 1/5

on all luminophores. All Al_2O_3 -Ce,Cr and Al_2O_3 -Ce,Fe luminophores were found to have in the emission spectrum a red band with $\lambda_{\text{max}} = 6920 \text{ \AA}$, the intensity of which depended upon the Cr and Fe contents. On an increase of the chromium content from 0.006 % to 0.1%, the intensity of the red band rose by the sevenfold, while that of the blue band decreased. At about $1 \cdot 10^{-2} \%$ the blue band becomes stronger again, and at $1 \cdot 10^{-3} \%$ the intensity of the red band is about 30% of that of the blue band. The afterglow lasts $1 \cdot 10^{-2}$ seconds. By introduction of Fe in Al_2O_3 -Ce, a sharp drop of intensity appears. Fe was found to act as an extinguisher, especially for the blue band, but also for the red one. The spectrum of the Al_2O_3 -Fe luminophore consists of two bands, one with $\lambda_{\text{max}} = 6920 \text{ \AA}$ and one with $\lambda_{\text{max}} = 5200 \text{ \AA}$, the former being a chromium band and having an intensity which is about 30% of the red band. Al_2O_3 luminophore has a green band on activation with copper or manganese. At a copper content of $2 \cdot 10^{-5} - 1 \cdot 10^{-3} \%$ this luminophore has an intensive green band with $\lambda_{\text{max}} = 5200 - 300 \text{ \AA}$. At about 1% Cu the intensity of the green band is

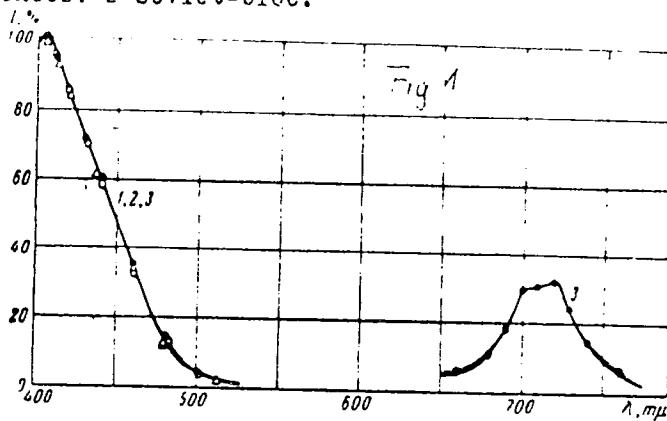

Card 2/5 X

Luminescence properties of ...

L0040
S/048/61/025/003/006/047
B104/B201

about 50% of that of the cerium band. The afterglow of these luminophores lasts 10^{-2} seconds. The use of spectrally pure aluminum oxide was found to raise the brightness of activator-free Al_2O_3 by about 20 - 25%. The afterglow in this case lasts ~ $1 \cdot 10^{-4}$ seconds. A.Ya. Gutner and Ye.K. Raspletina are thanked for measuring the luminescence characteristics of the luminophores, N.G. Karpel' for his spectroscopic analyses of aluminum oxide, and V.G. Sergeyeva for having prepared the luminophores. There are 2 figures and 4 references: 2 Soviet-bloc.

TITLE: On the effect of the preparation conditions on the formation of traps in ZnS
and ZnO base phosphors and the influence of predecomposition phenomena in solid solu-
tions of Cu₂O in ZnS on their luminescence /Report, Fourteenth Conference on Lumines-
cence Held in Riga, 16-23 September 1965/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 4, 1966, 637-643

TOPIC TAGS: luminescence, crystal phosphor, zinc sulfide, current carrier, luminophor

ABSTRACT: Introduction of new experimental methods has increased rather than reduced
the disagreement among different investigators regarding the structure of zinc sulfide
luminophors. On the basis of previous investigations of glow curves and the polarity
of the photocurrent carriers the authors showed that for the most part the discrepan-
cies are due to inadequate control of the synthesis conditions, i.e., that the phos-
phors studied by different groups differed as regards structure owing to uninten-
tional variations of the preparation conditions. Experiments show, for example, that
truly self-activated ZnS exhibits only one glow curve peak, but that if the compound

Cord 1/2

2-

L 26491-66

ACC NR: AP6013070

is exposed to oxygen, even at low pressure, during heating a second glow-curve peak appears and this is accompanied by change in the polarity of the photocurrent carriers (from n to p). Various experiments were carried out with pure, self-activated and impurity-activated ZnS and ZnO (including surface oxidized specimens) and several series of glow curves are reproduced. Data on the polarity of the current carriers in photoconductivity are also adduced. The curves and data demonstrate the effects of the synthesis conditions. A series of phosphors was prepared by heating different mixtures of ZnS with Cu₂S without flux at 1000°C, followed by reheating with quartz powder (to prevent caking) in sealed tubes at 1050°. These ZnS:Cu phosphors were studied immediately after preparation, after various heat treatments and after storage for some months at 20°. Their attributes differed considerably, again indicating the importance of synthesis and other conditions. It is pointed out that understanding of the peculiarities of the complicated chemical system constituted by copper-activated zinc sulfide luminophors requires further thorough investigation of the ZnS-Cu₂S-Cu system. TITLE: Investigation of the Electroluminescence and Photoluminescence Spectra of Phosphor Activated with Rare-Earth Elements (Issledovaniye elektricheskoi fotoluminestsentsii fosfora, aktivirovannogo reaktsionnymi elementami).

PERIODICAL: Optika i Spektroskopiya, 1953, V 1 N 3, p 304-306 (USSR)

ABSTRACT: The authors studied ZnS-Er and ZnS-Mn or phosphors with 4.3×10^{-4} g-atoms of Er and 1.7×10^{-4} g-atoms of Mn or Br per 1 mole of ZnS. The phosphors were prepared in a stream of wet H₂S at 1150°C. ZnS-Er calcium phosphor with 4.3×10^{-4} g-atoms of In per 1 mole of ZnS was also prepared. The presence of In produced a strong and characteristic orange-yellow emission as well as the appearance of red lines of thulium (present as an impurity in erium). The electroluminescence and photoluminescence spectra were recorded photoelectrically using the same equipment for both phosphors. The afterglow spectra (first afterglow) were recorded and measured rapidly with the same equipment. Fig. 1 contains the electroluminescence (EL)

...

Investigation of the Electroluminescence and Photoluminescence Spectra of
Barium Activated with Rare Earth Elements

and photoluminescence spectra of ZnS-Nd-Cu. Fig. 2 gives the electroluminescence spectra of ZnS-Er,Mn,Cu at voltages of 1000 (curve a) and 1600 V (curve b). Fig. 3 gives the photoluminescence spectra of ZnS-Er,Mn,Cu. Curve a was obtained at 1/10th of the excitation intensity used to obtain curve b. Fig. 4 gives the afterglow spectra of ZnS-Er,Mn,Cu. Again curve a shows the spectra obtained using 1/10th of the excitation intensity employed to produce curve b. Fig. 5 gives the ratio of intensities of the erbium line at 542 m μ and the maximum of the manganese band at 530 m μ for ZnS-Er,Mn,Cu. Curve a represents photoluminescence, curve b refers to the afterglow spectrum and curve c applies to electroluminescence. The following

Carlo 1/7

104/51-1-17
Investigation of the Electroluminescence and Photoluminescence Spectra of
Precipitates Activated with Rare-Earth Elements

Conclusions are reached by the authors: (A) The centres responsible for electroluminescence and photoluminescence of ZnS-Mn,C and ZnS-Er,Mn,C are the same and are similarly distributed throughout the lattice; (B) The mechanism of the phosphors studied is mainly due to electric field strengths ("normal" electrons); (C) The luminescence volume active in electroluminescence is about 7% of the volume active in photoluminescence. The authors thank Drs. A.N. Goryainov, I.M. Alekseyev and V.V. Fok for advice during the work and for references, 3 of which are cited.

UO/51-7-4-17/32

AUTHORS: Oranovskiy, V.Ye., and Khmelinin, B....

TITLE: Investigation of Electroluminescence of Zn-Cu Monocrystals.

PERIODICAL: Optika i spektroskopiya, 1959, vol 7, Nr 4, pp 542-546 (USSR)

ABSTRACT: Oranovskiy, Panasyuk and Redyushkin (ref 1), reported that in Zn crystals electroluminescence occurred in long narrow regions, called "dashes" and was concentrated at various spots along such dashes. The present paper reports further studies of these emitting "dashes". This was done by observing brightness (luminance) waves from various regions of the "dashes" and studying the effect of an ultraviolet light spot (100 μ in diameter, on the brightness waves. Electroluminescence was excited with 2000 v, 1500 c/s fields. It was found that electroluminescence was affected most strongly by ultraviolet spots of 365 m μ wavelength; 313 and 404 m μ light was less effective. To separate small regions of the crystal a microscope with diaphragms of various forms and dimensions was used. A comparatively long (1.2 mm) "dash" without any spots was used in these investigations. Visual observation of the "dash" showed that it consisted of several neighbouring sectors whose lengths varied from 40 to 300 μ . The boundaries of these sectors coincided very frequently with visible crystal defects, but the converse was not true. A photomultiplier and a two-beam oscilloscope were used

Card 1/2

201/31-7-4-17, 32

Investigation of Electroluminescence of Zn-Cu Monocrystals

to observe brightness waves from various sectors of the electroluminescent "dash". It was found that within one sector the position of the brightness wave maximum was constant with respect to the phase of the exciting voltage. When the exciting voltage frequency was altered the brightness-wave phase altered as well. The phases of brightness waves from neighbouring sectors were different: in all eight brightness waves with different phases were observed. For a given sector of the "dash" two brightness-wave peaks were observed in each excitation cycle (Fig 2a). On moving the ultraviolet spot towards this sector from one side, the first peak rose sharply while the other practically disappeared (Fig 2b). When the ultraviolet spot approached the sector from the opposite direction the first peak disappeared while the second was strengthened (Fig 2c). To observe the full effect of the ultraviolet spot usually less than 1 sec was required, but the return to the original picture of Fig 2a when ultraviolet radiation ceased took tens of seconds (Fig 3). In some cases ultraviolet irradiation produced, in addition to redistribution of intensity, a change in the brightness-wave phase. This is shown in Fig 4. The results obtained are interpreted as follows. The "dash" emits as a whole and various sectors correspond to regions of p- or n-type conductivity. Spots are assumed to occur at the points where p- and n-type regions meet. Since the 1.2 μm long "dash"

Card 2/3

Investigation of Electroluminescence of ZnS-Cu Monocrystals

SOV/51-7-4-17/32

extended between the capacitor electrodes, the authors deduce that electroluminescence can be produced by field intensities not greater than 10^4 V/cm. The latter value shows that, at least in the direction of the "dash", the electron paths may be up to two orders of magnitude greater than the mean free path. This agrees with the considerable rise of conductivity of electroluminescent monocrystals in the direction most favourable for electroluminescence (ref 2). Acknowledgment is made to Ye. I. Panasyuk for preparation of ZnS monocrystals. There are 5 figures and 2 references, 1 of which is Soviet and 1 English.

A THOU. Tverovskiy, Valer

TITLE: Investigation of the electroluminescence
based on Erb

PERIOD: Investigiya Akademii nauk SSSR - Seriya fizika, No. 5,
vol. 4, 1961, 716-718

TEXT: The paper, author was read at the 1st Conference on the properties of
crystal phosphors and, in addition to the investigation of the electroluminescence of the Erb. Cr. single crystal, it was proposed to present
paper to clarify the properties of the elementary processes of excitation by
excitation mechanism and the influence of the "impact" on the writer.
For this purpose, indicator has been found in the form of a
crystals at various positions of the probe with respect to the
non-homogeneous region of Erb. During these measurements the probe
probe has been directed towards the crystal regions located outside the
field of view. Indicators have been found under the following conditions:
without additional excitation with the lamp.

Carri 1/4

Investigation of the

Spectrum 2

photoprobe; 2) a position of the photoplate in the light circuit; 3) the direction, position and spot size of the light source; 4) the extent of the current density in the region concerned (current density is practically constant in the region of interest). It is being theorized that the ratio of the radiation intensity in the beam between the first and second regions of the light wave angle, close to the angle of the diffraction limit, is assumed that the main experimental point will be observed if this reason is due to a distortion of the beam caused by the crystal. A study of the irradiation unit shows that the ratio of the intensities of the two regions is nearly inversely increasing or decreasing the angle of the beam. The ratio of the intensities of the two regions of the beam is also observed. Therefore, it may be assumed that the main cause of the change in the ratio of the intensities of the two regions is the influence of the photoplate on the beam. The results of the experiments have shown that the ratio of the intensities of the two regions has been increased by 1.5 times when the photoplate was activated with iodine vapor.

Investigation of the...

reaction of the gaseous phase of zinc- and hydrogen sulfide. The activation of copper and manganese took place during the growth of the crystal. These crystals showed the same distribution character of luminescence during the electroluminescence as has been found in crystals investigated earlier. The luminescence was concentrated on single parallel lines. The lines of copper luminescence are blue those of manganese luminescence are red. It has been found that manganese lines will react not at all or much less than copper lines on the effect of the photo probe. The fact that the luminescence of manganese is independent of the effect of the photo probe proves that the luminescence of copper will take place during the semicycle voltage, which follows the excitation. This also confirms the statement that the processes of the field concentration are independent in a wide range of the number of additionally introduced charge carriers having either sign, and that the excitation of the electroluminescence centers in these crystals will take place in the high-voltage region of the electric field. There are 2 figures and 3 Soviet-bloc references.

TITLE: Investigation of electroluminescence of single crystals of zinc sulfide

SOURCE: Optika i spektroskopiya, v. 18, no. 3, 1965, 474-478

TOPIC TAGS: electroluminescence, zinc sulfide optical material, single crystal, luminescence center, luminescence excitation

ABSTRACT: This is a continuation of earlier work by one of the authors (Oranovskiy et al., Inzh.-fiz. zhurn. no. 3, 39, 1959; Opt. i spektr. v. 7, 543, 1959; Izv. AN SSSR, ser. fiz. v. 25, 516, 1961), in which it was shown that individual sections of the glowing lines produced when single-crystal ZnS-Cu,Cl is excited with alternating field glow at different phases of the exciting voltage. The purpose of the present investigation was to determine more clearly the connection between these electroluminescence lines and structural or electrical inhomogeneities in the crystal, and to determine whether application of the electric field causes impact ionization or the tunnel effect in the crystal. The observation and the measurements were carried out with a microscope, and the electroluminescence was excited

Card 1/2

L 43860-65

ACCESSION NR: AP5006436

by the edge field of a capacitor or with the aid of contacts, the exciting voltage having a frequency of 1300 cps. The measurement procedure was also similar to that used in the earlier investigations. The probe was a light spot 50 mm in diameter of ultraviolet light at 365 mm wavelength. An ac and a dc field could be applied to the crystal simultaneously with photoexcitation by means of the probe. The radiation was recorded with a photomultiplier and an oscilloscope. The results show that the glow lines are formed in the regions of electric-field concentrations on the boundaries between the areas where changes take place in the conductivity of the crystal ($n'-n-n'$ regions where $n > n'$, analogous with p-n-p junctions in semiconductors). An investigation of the variation of brightness with amplitude as a function of the additionally applied constant field has shown that the excitation and ionization of the luminescence centers are produced by cascade-impact mechanism rather than by a tunnel effect. Orig. art. has: 1 figure and 1 formula.
